

The Future POPULATION of India

A Long-range Demographic View

Population Foundation of India

Population Reference Bureau

August 2007

PREFACE

India's population passed the one billion mark in 2000 and, this year, celebrated its 60th year as an independent country. Its population is likely to pass China's as the world's largest within 20 years. All of this leads quite naturally to the question: how large might the population of the world's largest democracy become?

This is the question that the Population Foundation of India and its partner, the Population Reference Bureau, have addressed in an exercise to project India's population for the long term. While no one can predict future events with certitude, it is possible to examine the consequences of possible future trends in demographic rates, with the future birth rate a significant factor.

In this publication, two scenarios of India's future population are offered. Both assume that fertility will decline continuously to the point where couples average two children each, the goal of India's National Population Policy 2000. The scenarios differ in one respect: one assumes that states with higher current fertility will decline to the "replacement level" of 2.1 children, a common assumption in projections. The second assumes that the decline will continue to 1.85 children, near the level observed in states such as Kerala. The first scenario results in an India of two billion population while the second falls short of that mark and results in eventual population decline.

We hope that this exercise forms the basis for useful discussion and consideration of what challenges might lie ahead and how those challenges might be addressed.

A. R. Nanda
Executive Director
Population Foundation of India

We are happy to have collaborated with the Population Foundation of India in this important research. A country's future population size, its geographic distribution and its age composition are among its most significant future considerations.

Projecting any country's population in the long term is an obvious challenge and one that increases the further one ventures into the future. Yet, in demography, future developments result from past events. India's present population is a consequence of trends in birth and death rates observed in the past. As a result, its future is partly determined by its age structure, by the number of young people who will be tomorrow's parents.

In India, fertility rates have exceptionally wide variation, from an average of only 1.7 children in Kerala to 4.3 in Bihar. Such a wide range adds additional uncertainty to any population projection. But, at the same time, it adds to the importance of evaluating the country's possible population future. In this exercise, we have made the fundamental assumption that fertility will continue a smooth decline to near the two-child average in states where it is now above that level. Should that assumption prove true, we must also consider the question of how low future fertility might be.

Is an India of two billion population a possibility? In this exercise, we have looked at how such an event might come about and have drawn two potential portraits of India's population future.

THE FUTURE POPULATION OF INDIA

A LONG-RANGE DEMOGRAPHIC VIEW

India has made great strides in its official goal to slow population growth since the inception of its population programme in 1952. In 1950, women in India averaged about six children each in their lifetimes. Today, that average has dropped to about three. India stands at a unique point in her population history. Both the potential for a continuation of a declining population growth rate and the certainty of adding many hundreds of millions to the population due to population momentum exist side-by-side. It is now virtually certain that India will be the world's largest country in population, surpassing China. At independence, India's population was 350 million. Today, it stands at 1.1 billion. But how large might it become? Could India's population reach two billion, the only country likely to do so?

The purpose of this exercise is to provide glimpses into India's long-term population future, projecting population from 2001 to 2101. Such a period is quite lengthy, but future population size is a direct result of demographic trends generations before. While projections for a closer time period are more likely to prove accurate, long-range consequences are necessarily obscured. Recognizing this fact, two projection scenarios were prepared for this project in order to provide more than a single possible outcome. The use of two scenarios also avoids the trap of an odd number of projections. In that case, one will often be considered the "middle," and, by implication, the most reasonable, while the other two possibilities, the higher and lower projection, will be ignored. A two-projection exercise requires us to consider the *assumptions* that underlie each projection more seriously, a process that should always precede looking at the results.

A second purpose of this exercise is to project India's population state-by-state, summing to the national total, so that the consequences of differing future trends in statewise fertility can be seen. The national average total fertility rate (TFR) hides a wide spectrum of state-level differences. The TFR, or the average number of children a woman would have in her lifetime at the birth rate of a given year, currently ranges from 1.7 in Kerala to 4.3 in Bihar. Low-fertility states such as Kerala and Tamil Nadu will contribute little to future population growth and are likely to decline in size. It is in the higher fertility states, such as Bihar, Jharkhand, Madhya Pradesh, Rajasthan, Uttar Pradesh and others that the story of India's future population size will be told. By projecting population statewise, the effect of higher-fertility states on the national growth rate can be taken into account as they grow larger in comparison to the low-fertility states..

The Nature of Projections

Population projections are not true forecasts of future population, but scenarios that result from the assumptions made when they are prepared. Assumptions must be made about declines in the future birth rate (fertility), improvements in mortality (life

expectancy at birth and infant mortality), and migration into or out of an area. For India, assumptions made about future fertility trends are of the greatest importance. Mortality has declined to the point where life expectancy at birth nationwide has risen to 64 years. While mortality is likely to continue to improve, its contribution to future population size will be less important than fertility.

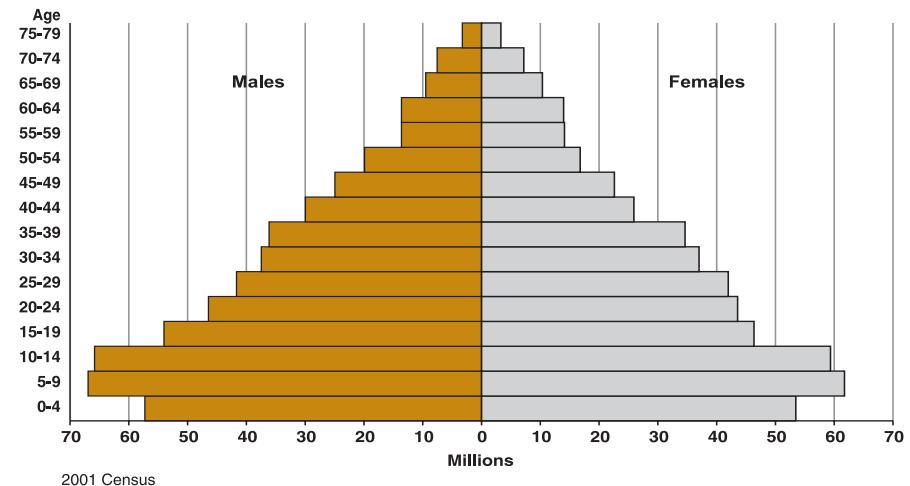

A fundamental principle for this project was to perform the projections with consistency of method and clarity for all 35 states and Union territories. Thus, future fertility trends were projected in the same way for all states, as detailed below. Some exceptions were necessary in migration assumptions for "city-states," such as Chandigarh and Delhi.

The projections were performed using the standard cohort-component method, i.e., by projecting populations by sex and individual age groups. The FIVFIV projection program, developed by the Population Council, was utilised.

Base Population

The population of each state used as the starting point, or base population, for the projections is that of the 2001 Census of India by five year age groups and sex. As in the majority of developing countries, data by age and sex in India suffer from a number of deficiencies. For one, large numbers of people do not know their age, females appear to be undercounted, and young children are under-represented. The youngest age group, ages 0-4, is undercounted or partially omitted, as can be seen in the population pyramid for all-India in Figure 1.

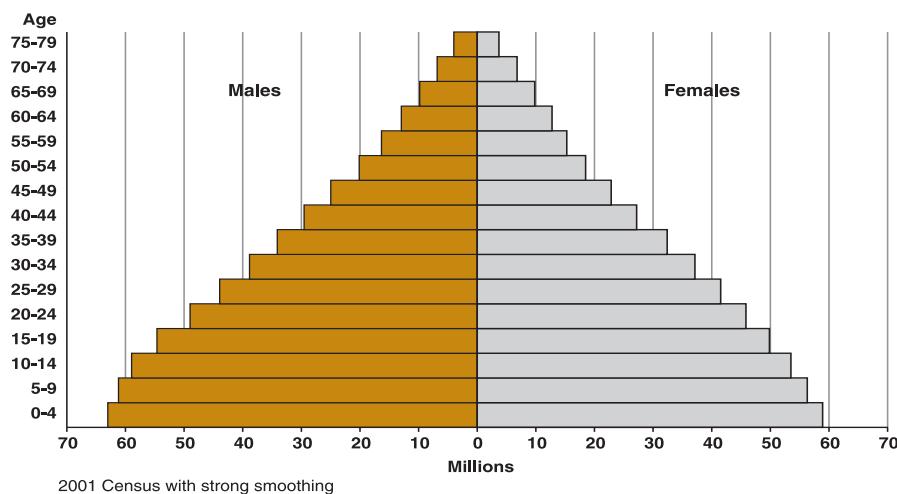

Figure 1: Population of India, 2001 Census, Unsmoothed

THE FUTURE POPULATION OF INDIA A LONG-RANGE DEMOGRAPHIC VIEW

The first step in determining the base populations was to conduct an analysis of the accuracy of age-sex reporting. Having done so, the standard demographic technique is to “smooth” populations by age, removing as many anomalies as possible from the published figures. For this and other procedures, the Population Analysis Spreadsheets (PAS) developed by the U.S. Census Bureau were used. This process produces a population age structure that more closely resembles the true situation, but perfection will always remain elusive. The smoothed population of India is shown in Figure 2.

Figure 2: Population of India, 2001 Census, Smoothed

Fertility Assumptions

A key concept in fertility is that of *replacement level* fertility. This is often referred to as the “two-child norm.” When couples have but two children, they merely replace themselves, not increasing the size of successive generations. When this replacement level is reached, a population will eventually cease growing and enter a “zero-growth” condition. A TFR of 2.1 is usually specified as the replacement level. This is 2.1 rather than 2.0 since not all women survive to the end of their childbearing years so that women who do must compensate and because, worldwide, there are 105 male babies born for every 100 females, the normal sex ratio at birth.

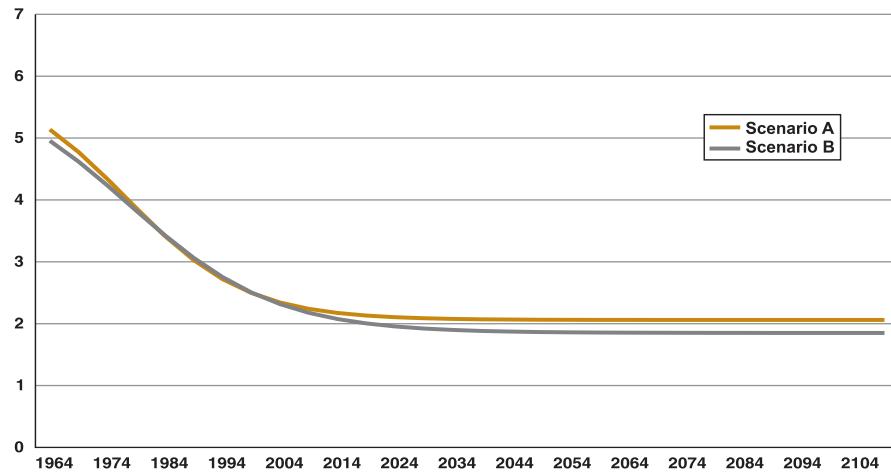

Two population scenarios, labeled A and B were prepared. These differ in only one respect, the “target” TFR, used as a final value. Scenario A, the higher of the two, makes the assumption that 2.1, the classic replacement level fertility value, will be the final value for states where it is currently above 2.1. In Scenario B, the target is 1.85 for those states above that value. For states with very low TFRs, such as

Kerala and Tamil Nadu, the TFR was assumed to remain constant throughout the projection period.

Having decided on the target values, it is then necessary to determine the path that the assumed fertility decline will take. Will it remain at a higher level and decline suddenly to a lower level? Will it decline only very gradually? As a low value, such as 2.1, is approached will the decline slow? Since the pattern of decline cannot be fully anticipated, a standard curve used in population projections was employed. The logistic curve has often been observed to give a useful approximation of how fertility has declined worldwide. Once decline has begun, it often continues at some steady pace, slowing as lower values are approached. This pattern has also been observed in the low fertility states of India.

The U.S. Census Bureau software utilizes the past trend in a state’s fertility decline pattern to project future decline along the logistic curve. Figures 3 and 4 illustrate this process for two states, Karnataka, a state with relatively low current fertility, and Uttar Pradesh, a state with relatively higher fertility. The past trend in the TFR was taken from India’s Sample Registration System (SRS), a data collection

Figure 3: Total Fertility Rate, Karnataka, 1964 - 2104

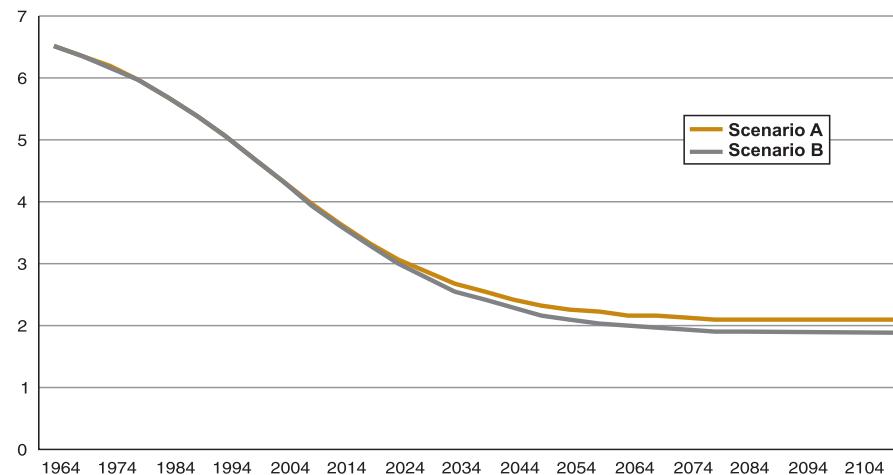

programme virtually unique among developing countries. Since the early 1970s, the SRS has sampled millions of households each month to inquire about the number of births and deaths that had occurred. As a result, the SRS is able to produce estimates of India’s annual birth, death, infant mortality rates and TFRs as well as recurring sets of life tables. In the case of the TFR, estimates are produced only for bigger states. For smaller states and Union territories, TFRs were estimated by reverse projection of

THE FUTURE POPULATION OF INDIA

A LONG-RANGE DEMOGRAPHIC VIEW

Figure 4: Total Fertility Rate, Uttar Pradesh, 1964 - 2104

smoothed 2001 Census populations and by matching the SRS crude birth rates (births per 1,000 population), which are produced for smaller states and Union territories.

Sex Ratio at Birth

The sex ratio at birth, or the number of girl babies born per 100 males, has emerged as a significant issue in India due to the practice of pre-birth sex selection and the abortion of female fetuses. In recent years, the Indian government at the national and local level has introduced a variety of incentives and disincentives to curtail this illegal practice. For the projections, it was assumed that the sex ratio at birth would return to a global normal value of 95 female births per 100 male births during the first 35 years of the projection.

Mortality

Life expectancy at birth in India ranged from 57 years in Madhya Pradesh to 74 years in Kerala in 2002-2004. Similarly, infant mortality ranged from 14 infant deaths per 1,000 live births in Kerala to 76 in Madhya Pradesh in 2005. For the projections, life expectancy was projected in the same manner as fertility, using a logistic curve and incorporating Registrar General life tables up to 1999-2003 as input values. Target values of life expectancy were 85 years for males and 90 years for females, typical assumptions made in projections worldwide, although there is much debate on the issue of just how long the human life span may ultimately be. For the projection, widely-used model life tables, Coale-Demeny Model Life Tables, provided the basis for projections of mortality. The model life tables themselves are available in four groups, each with varying levels of infant mortality for the same level of life expectancy. During

the projection process, the selection of a particular group of life tables was matched as closely as possible to reported SRS infant mortality in each state. For smaller states and Union territories, life tables were selected from those for the bigger states with similar mortality levels.

The future impact of HIV/AIDS was not incorporated into the projections due to the lack of useable information on statewide data such as AIDS death rates which would be required. Population projections from the National Commission on Population did incorporate HIV/AIDS at the national level and projected that the country's population would be 16 million less with HIV/AIDS than without in 2026. Since those projections were performed, the National AIDS Control Organisation has lowered its estimate of HIV prevalence from 0.9 to 0.36 percent of the population ages 15-49. Users of the PFI/PRB projections may wish to take these factors into account.

Migration

Migration presents particular challenges in a population projection due to its often unpredictable nature. Net migration figures for states are available from Indian censuses and these were used as a basis for the projections. It was assumed that interstate migration would increase slowly in absolute terms from that observed for 1991-2001 from the 2001 Census and then slowly decrease, the latter a common assumption in projections. Significant adjustments had to be made to the migration assumptions for Chandigarh and Delhi, which would become impossibly large under the standard assumption. It was assumed that much migration to these areas would be diverted to adjacent suburban areas such as Gurgaon in Haryana and Noida in Uttar Pradesh. In these cases, in-migration into Haryana was increased and out-migration from Uttar Pradesh decreased. Since the census cannot interview those who have left India, an adjustment was made to reconcile state-level migration to an assumed national annual net emigration level of approximately -200,000. State-level migration is an area which commands considerably more research and analysis.

Results

Population projections are not forecasts, as stated earlier. They are scenarios of future population size which result from the situation today and the assumptions made concerning future trends. Nonetheless, projections have value. There are, after all, some reasonable bounds to expectations. It is expected that fertility in the higher-fertility states will decline as it has in other states. It is expected that life expectancy at birth will continue to improve. In the absence of a very sharp and unanticipated shift in mortality trends, it is future fertility trends that will determine India's future population size.

It is useful to compare the results obtained in this exercise with results obtained by other organizations. The 2006 National Commission on Population Projections

THE FUTURE POPULATION OF INDIA A LONG-RANGE DEMOGRAPHIC VIEW

projected the population of India and bigger states to the year 2026. The 2026 projected population that resulted is 1.40 billion. This can be compared to the Scenario A population of 1.46 billion and that of Scenario B, 1.45 billion. The United Nations Population Division (UNPD) also produces a projection of the total population of India in three variants, low, medium and high. For 2025, these range from 1.37 to 1.55 billion. The UNPD extends their projections to 2050 and those projections range from 1.39 to 1.96 billion compared to Scenario A's 1.81 and Scenario B's 1.74 billion in 2050. A summary of the results is given in Table 1 and shown graphically in Figure 5.

Table 1. Projected Population of India, Two Scenarios (millions)

	2001	2026	2051	2101
Scenario A	1,029	1,464	1,825	2,181
Scenario B	1,029	1,449	1,751	1,853

Scenario A, with a final TFR of 2.1 for higher fertility states, results in a population that does, in fact, reach two billion, a milestone that would occur in 2066-2071. By the end of the projection period, in 2101, four states, today's Bihar, Madhya Pradesh, Rajasthan and Uttar Pradesh would account for almost half of the country's population. Scenario B, with a final TFR of 1.85, does not reach two billion. Under Scenario B, growth peaks in 2081-2086, after which it begins a period of population decrease. Statewise detail is provided in the tables.

It is interesting to note that some states of India may experience a new phenomenon, population decline. The populations of Kerala and Tamil Nadu would begin to decline in the 2041-2051 period while those of Andhra Pradesh and West Bengal would do so around 2061 under Scenario B. A second new development is substantial future ageing. By 2051, the population ages 65+ would exceed that ages 0-14 by 2041 in Kerala and Tamil Nadu and that of India by 2091 in Scenario A and 2071 in Scenario B.

Which scenario is more likely? Different users will have different opinions as to the appropriateness of the scenarios as they apply to each state. Some, for example, may feel Scenario A appropriate for Bihar, but not Uttar Pradesh. Over such a long period, many different events may influence population trends. States with low fertility today may become concerned about population ageing and decline and encourage more births. Such a turnaround may seem unlikely today, yet precisely this has happened in some countries of Asia which once advocated lower birth rates. Pressure on the availability of agricultural land may cause accelerated migration to urban areas and result in faster fertility decline. Perhaps, continuing son preference will act to keep fertility somewhat higher. And it may simply be that a TFR as low as 2.1 may never be reached in some states. If, for example, fertility declined in Uttar Pradesh, not to 2.1, but to 2.5, its population in 2101 would reach 653 million, not 480, as in Scenario A. While long-range projections necessarily require long-range assumptions, their value is that they can quantify the consequences of future demographic trends that could not otherwise be foreseen.
